

# Hydride and Dihydrogen Ligands

- First Hydride Complex =  $[\text{FeH}_2(\text{CO})_4]$  – Hieber, 1931
- First Dihydrogen Complex =  $[\text{Mo}(\text{H}_2)(\text{CO})_3(\text{PCy}_3)_2]$  – Kubas, 1983

## Characterization of Metal-Hydrides:

- $^1\text{H}$  NMR  $\rightarrow$  0 to  $-60$  ppm for non  $d^0$ -complexes (0 to  $+10$  for  $d^0$ )
  - $\rightarrow$  coupling to M (e.g. Pt or Rh) or co-ligands (e.g.  $\text{PR}_3$  can be useful)
  - $\rightarrow T_1$  (dipole-dipole)  $\propto r^6 \rightarrow > 100$  ms
- IR  $\rightarrow \nu(\text{M-H}) = 2200\text{-}1500 \text{ cm}^{-1}$ , but can be weak (therefore unreliable) – deuterium labeling can help
- X-Ray  $\rightarrow$  Hydrides difficult to detect and M–H underestimated.
- Neutron Diffraction  $\rightarrow$  V. Useful, but not readily available; large crystals required ( $1 \text{ mm}^3$  vs  $0.01 \text{ mm}^3$ )

### Early TM Hydrides = hydridic

### Late TM Hydrides = can be quite acidic (especially with low valent metals)

# Synthesis of Hydride and Dihydrogen Ligands

**Protonation :**

**From H<sup>-</sup> donors:**

**By Oxidative Addition (e.g. from H<sub>2</sub> or HSiR<sub>3</sub> or HBR<sub>2</sub>)**

**By σ<sup>-</sup>Bond Metathesis (typically early TM alkyl + H<sub>2</sub>)**

# Hydride and Dihydrogen Ligands

- $M(H_2)$  = a type of  $\sigma$ -complex
- $\nu(H-H) = 2300-2900\text{ cm}^{-1}$  but often weak
- $^1H$  NMR = 0 to  $-10$  ppm (often broad)
- $T_1(\text{dipole-dipole}) \propto r^6 \rightarrow <40\text{ ms}$
- $^1J_{H,D}$  for  $M(HD) = 20-30\text{ Hz}$ , versus  $43\text{ Hz}$  for free  $HD$  and  $\sim 1\text{ Hz}$  for  $M(H)(D)$
- Both interactions weaken the H–H bond
- Typical H-H distances in  $M-(H_2)$  complexes are  $84-90\text{ pm}$  (vs  $74\text{ pm}$  in free  $H_2$ )
- Metals capable of strong  $\pi$ -backdonation and with an accessible oxidation state 2 units higher (e.g.  $Ir^I \rightarrow Ir^{III}$ ) can break the H–H bond to give a dihydride.
