

# Classification of Ligands: II

## The L, X, Z approach

Malcolm Green : The CBC Method for Covalent Bond Classification used extensively in organometallic chemistry.

- L** ligands are derived from charge-neutral precursors:  $\text{NH}_3$ , amines, N-heterocycles such as pyridine,  $\text{PR}_3$ , CO, alkenes etc.
- X** ligands are derived from anionic precursors: halides, hydroxide, alkoxide alkyls—species that are one-electron neutral ligands, but two electron donors as anionic ligands. [EDTA](#)<sup>4-</sup> is classified as an  $\text{L}_2\text{X}_4$  ligand, features four anions and two neutral donor sites.  $\text{C}_5\text{H}_5$  is classified an  $\text{L}_2\text{X}$  ligand.
- Z** ligands are RARE. They accept two electrons **from** the metal center. They donate none. The “ligand” is a Lewis Acid that accepts electrons rather than the Lewis Bases of the X and L ligands that donate electrons.

## Electron Counting for simple molecules

Whenever you see a metal complex, work out:

- Metal oxidation state (organic chemistry knowledge will help assign the correct charges to the ligands).
- $d^n$  Electron configuration (remember, all valence electrons are d-electrons)
- Electron count for the complex

(Vaska's compound)

Chris Cummins (MIT) →

$$\text{Ir}^+ = d^8$$

$$\text{Cl}^- = 2$$

$$2 \times \text{PPh}_3 = 2 \times 2 = 4$$

$$\text{CO} = 2$$

$$\text{Total} = 16$$

$$\text{Mn}^+ = d^6$$

$$\text{I}^- = 2$$

$$5 \times \text{CO} = 5 \times 2 = 10$$

$$\text{Total} = 18$$

$$\text{Hg}^{2+} = d^{10}$$

$$\text{Br}^- = 2$$

$$\text{Me}^- = 2$$

$$\text{Total} = 14$$

$$\text{U}^{4+} = d/f^2$$

$$3 \times \text{NR}_2^- = 3 \times 2 = 6$$

$$\text{SiR}_3^- = 2$$

$$\text{Total} = 10$$

# Alternative methods for electron counting

## Method A

assign charge to metal

$$\begin{aligned} \text{Ir}^{3+} &= d^6 \\ 2 \times \text{Cl}^- &= 2 \times 2 = 4 \\ \text{Ph}^- &= 2 \\ 2 \times \text{PPh}_3 &= 2 \times 2 = 4 \\ \text{CO} &= 2 \\ \text{Total} &= 18 \end{aligned}$$

$$\begin{aligned} \text{Au}^+ &= d^{10} \\ 2 \times \text{CN}^- &= 2 \times 2 = 4 \\ \text{Total} &= 14 \end{aligned}$$

## Method B

ligands and metal neutral

$$\begin{aligned} \text{Ir} &= d^9 \\ 2 \times \text{Cl} &= 2 \times 1 = 2 \\ \text{Ph} &= 1 \\ 2 \times \text{PPh}_3 &= 2 \times 2 = 4 \\ \text{CO} &= 2 \\ \text{Total} &= 18 \end{aligned}$$

$$\begin{aligned} \text{Au} &= 11 \text{ electrons} \\ 2 \times \text{CN} &= 2 \times 1 = 2 \\ 1\text{-charge} &= 1 \\ \text{Total} &= 14 \end{aligned}$$

- PH generally recommends this method, though sometimes problems exist

**IMPORTANT:** whichever method you use, be consistent !!!

## Electron Counting Practice – Examples

Borole = dianionic version of Cp<sup>-</sup>

Q = How should the μ<sub>3</sub>-I<sup>-</sup> ligands be counted ?

SiMe<sub>2</sub>(C<sub>5</sub>H<sub>4</sub>)<sub>2</sub><sup>2-</sup> is just two Cp<sup>-</sup> anions joined together

Q = How should the Ru-Ru bond be counted ?

Q = how should the bridging carbonyls be counted ?
